### **Abstract**

The COVID-19 pandemic, resulting from the SARS-CoV-2 virus, continues to impact the daily lives of individuals worldwide. Although research has been conducted on long-COVID symptoms, the underlying causes remain unclear. Notably, instances of neurological decline have been observed following SARS-CoV-2 infections. 125,573 articles regarding neurological damage and cognitive dysfunction were published and can be found from major research databases. For this scholarly project, 25 peer-reviewed journal articles pertaining to long-COVID and neurologic function changes, as well as potential underlying reasons for these changes, were curated. The proposed hypotheses include the virus' ability to pass through and harm the blood-brain barrier and neuronal cells, the release of neurochemicals associated with the SARS-CoV-2 antibody spike protein, as well as vascular ischemia, hypoxia of the brain, and other organs. Urgent attention is required to conduct further research on the treatment of chronic neurologic function changes resulting from long-COVID.

*Keywords:* COVID-19, SARS-Cov-2, brain function, brain fog, cognitive function, brain damage, neurologic damage, hard to concentrate, memory loss, long-COVID

## SECTION ONE: INTRODUCTION

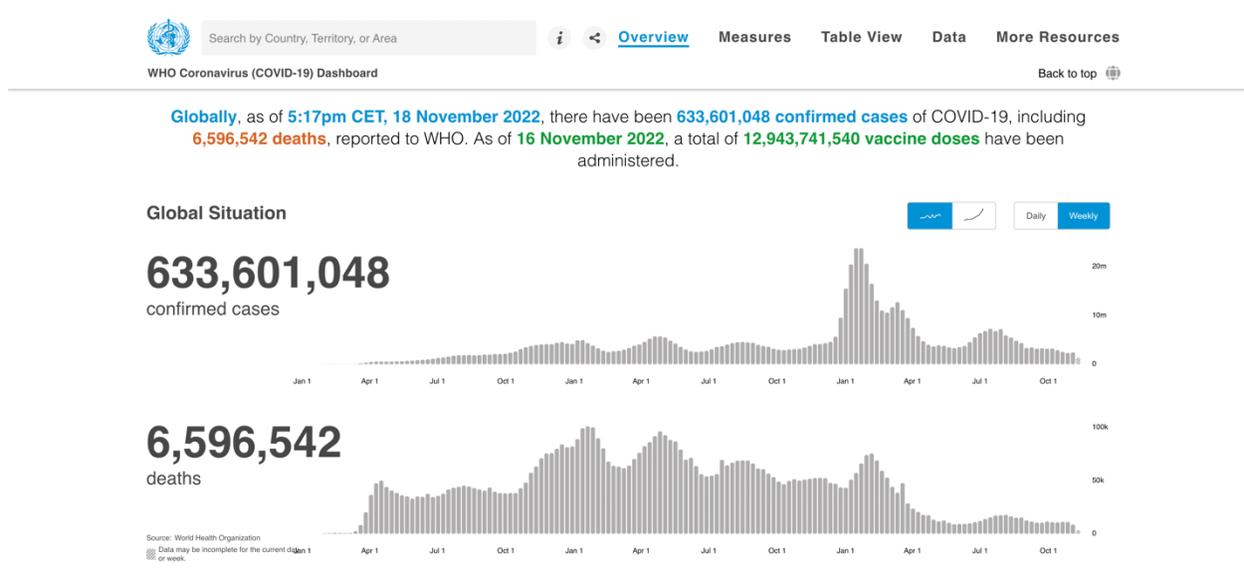

### Background

COVID-19, which is caused by the novel coronavirus SARS-CoV-2, has been responsible for the ongoing pandemic (Feehan & Apostolopoulos, 2021). It is still not entirely or clearly understood what COVID-19 pathogenesis is and how it causes the damage of the human body (Paludan & Mogensen, 2022). More research has been conducted and new data have been analyzed for further understanding of COVID-19 (Paludan & Mogensen, 2022). Based on the data from the World Health Organization (WHO), as of November 18, 2022, there have been 633,601,048 confirmed cases of COVID-19 (including 6,596,542 deaths) globally and 96,752,266 confirmed COVID-19 cases in the US (including 1,064,975 deaths), that have been reported to the WHO (World health Organization [WHO], n.d.). Figure 1 and Figure 2 show more details with trends (WHO, n.d., Overview section). These numbers are likely incomplete due to US and other countries' COVID testing and treatment policies. Many sick patients are refusing to be tested for COVID-19, and the home-based rapid tests are known to produce false negative results. Even if a person receives a positive result from a home rapid test, they typically do not report it to the CDC either because they lack knowledge about how to report it or they refuse to do so. As a result, many home-based rapid test results go unreported unless people seek help from healthcare providers.

COVID-19 is becoming one of the worst pandemics in human history, without any indication of slowing down; and this is despite breakthroughs with current vaccines (Feehan & Apostolopoulos, 2021). Figure 3 shows the historical timeline of major pandemics with upper and lower estimates of deaths (Feehan & Apostolopoulos, 2021, Figure 3).

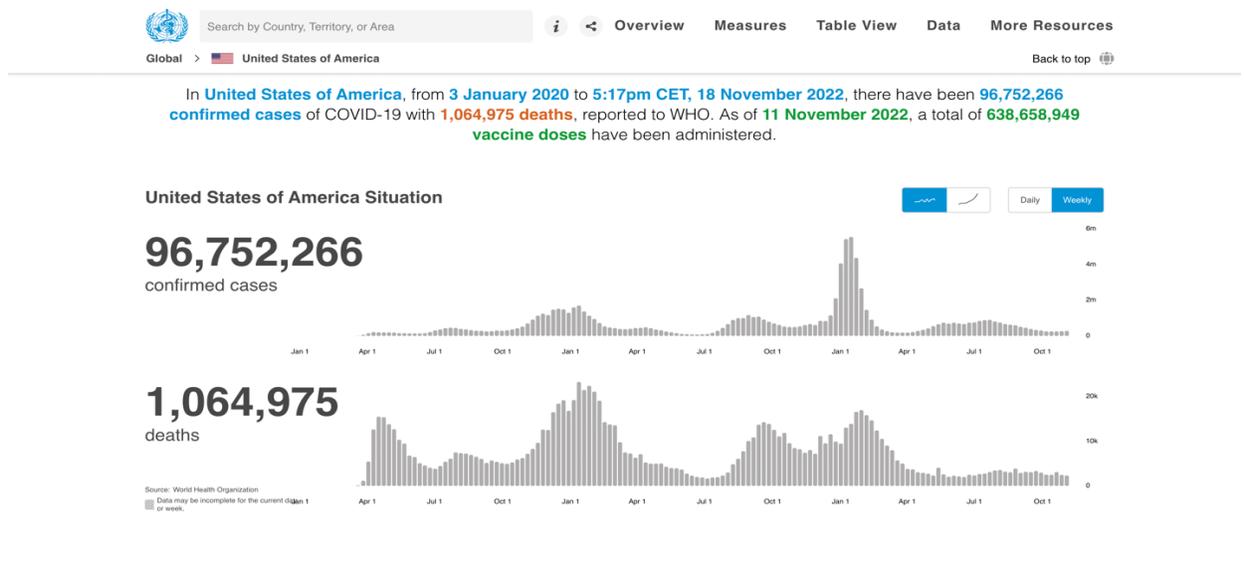

**Figure 1**

**Figure 3**

*Historical Timeline of Major Pandemics with Upper and Lower Estimates of Deaths (Feehan & Apostolopoulos, 2021)*

**Problem Statement**

Generally speaking, it is extremely hard to avoid hysteresis and incompleteness in epidemiological data collection. As this pertains to the ongoing COVID-19 pandemic, the real number of COVID -19 infections and deaths could be much higher than the numbers we see in public publications. Despite the diligent efforts of epidemiologists and frontline healthcare professionals to ensure data accuracy, there may be numerous reasons for discrepancies. COVID-19 infection does not only pose the risk of death, as numerous research efforts and studies have highlighted potential long-term complications that can affect multiple body systems such as the heart, lungs, kidneys, skin, and brain, among others. (Center for Disease Control and

Prevention [CDC], n.d.). It has been extremely challenging for countries' top leaders to create guidelines for people to follow them globally. It may be totally different strategies using for disease control between countries, such as the U.S. and China. Today, it may still be difficult to judge which view is better or correct. The answer to these questions may be explored for many decades.

### **Purpose of the Project**

The purpose of this evidenced-based practice (EBP) project is to identify a possible relationship between COVID-19 infection and neurologic damage which is represented by decline of cognitive function in adult population. This integrative review project started with research of databases of peer-reviewed journal articles related to COVID-19 and brain function changes.

### **Clinical Question**

To form the clinical question in this integrative review, the PICO framework (representing patient/problem/population, intervention, comparison, and outcome) was used. As this project does not involve intervention, the focus is on COVID-19 infected patients; and specifically on the neurological damage that may occur post-infection, which can be evaluated through cognitive tests or imaging studies. The comparison will be made between cognitive function or changes in brain scans before and after infection, and the outcome will be to determine if COVID-19 causes brain damage and reduces cognitive function. Thus, the PICO statement is "Whether SARS-CoV-2 infections affect human cognitive function?"

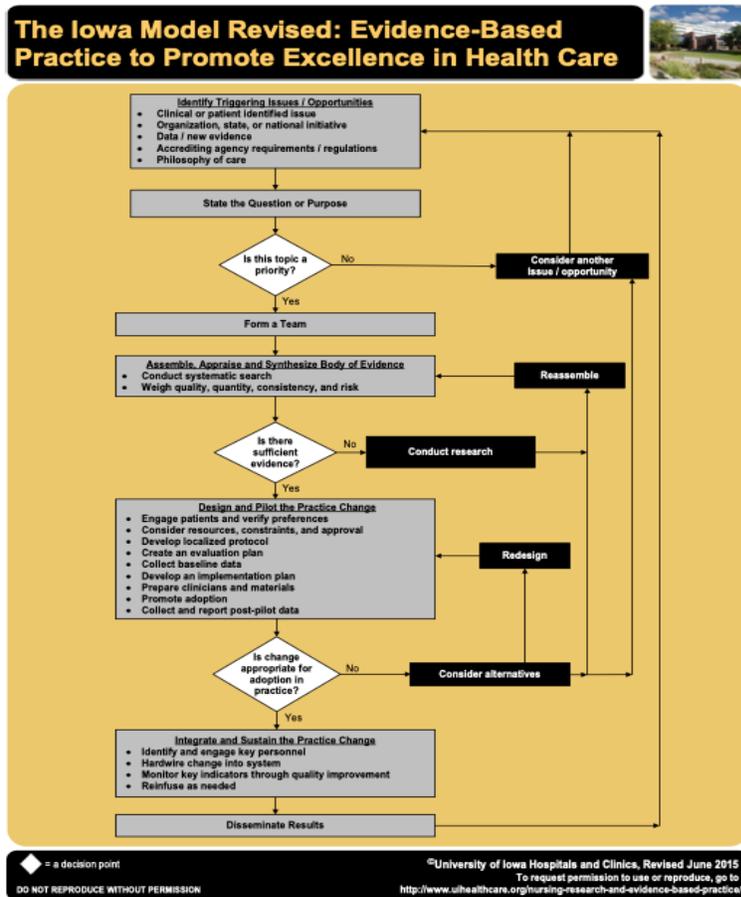

### **Conceptual Framework/Model**

The Iowa model is a valuable tool for analyzing and implementing evidence-based practice that was used in this scholarly project. In the Iowa Model, the first step is identifying the

triggering issue and form a question or purpose of potential changes; if it is a priority, then form a team to do research for existing studies and see whether there is sufficient evidence to support the change. After completing this, the next step is to either conduct new research, or make a plan of change (Buckwalter et al., 2017). The literature review offers data to be considered for the next step. The articles listed above clearly support the relationship between SARS-CoV-2 infection and some neurologic and other long-COVID symptoms. Therefore, it could be considered enough evidence to craft a plan of a change. If there is no higher-level quantitative study or the quantitative study only proves the relationship without detailed improvement rates from a literature review, then more detailed quantitative research should be designed and conducted before planning any changes to a practice.

**Figure 4**

*The Iowa Model*

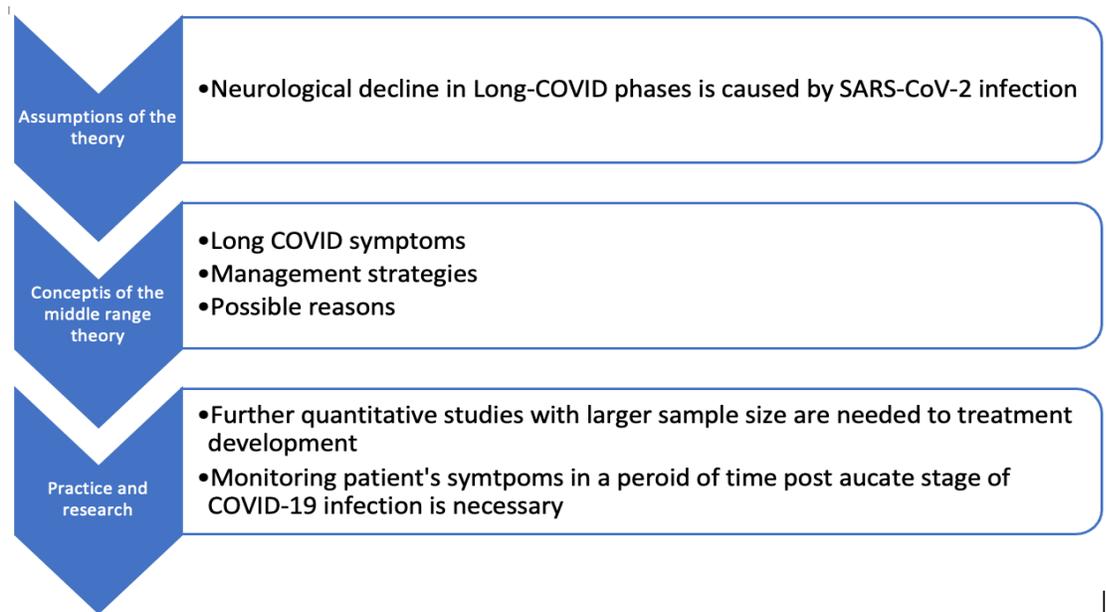

**Theoretical Framework**

The Symptom Management Theory was developed by a group of authors, namely Bender, Janson, Franck, and Lee, who are affiliated with the University of California, San Francisco Symptom Management Faculty Group. Based on the interactive-integrative paradigm, the theory proposes that symptom management is a result of people's interaction with their environment. It assumes that health and illness have an impact on symptom management, and that improvements in symptoms go beyond personal health. Additionally, the theory suggests that symptoms are subjective and often experienced in clusters. There are three concepts in this theory: symptom experience, symptom management strategies, and symptom status outcomes. Practice based on this theory emphasizes patient-provider communication and focused on provider understanding patient’s symptoms experience and offering effective strategies. On the

other hand, research based on this theory includes measurement of symptom-specific outcomes and contextual factors related to the symptom under study (Smith & Liehr, 2018).

**Figure 5**

*The Symptom Management Theory*

**SECTION TWO: COMPREHENSIVE AND SYSTEMATIC SEARCH**

**Search Organization and Reporting Strategy**

This study utilized Liberty University's online library to conduct systematic research. Given the focus on databases specializing in medical content, only high-quality articles from such databases were considered for the search. Ultimately, the study selected CINAHL, PsychINFO, PubMed, ProQuest, and Web of Science databases to be used. In order to choose high quality articles, only peer reviewed journal articles were selected at initial search. Time sensitivity is considered as a part of quality control for selecting articles. In this study, five-year was chosen as a time marker.

Overall, this systemic research using CINAHL, PsychINFO, PubMed, ProQuest, and the Web of Science databases, focused on peer reviewed journal articles which were published within five years.

### **Key Words and Terminology**

The key words for searching the articles were COVID-19, SARS-Cov-2, brain function, brain fog, cognitive function, brain damage, neurologic damage, hard to concentrate, memory loss, long-COVID.

*COVID-19* refers to “a mild to severe respiratory illness that is caused by a coronavirus (Severe acute respiratory syndrome coronavirus 2 of the genus Beta-coronavirus), is transmitted chiefly by contact with infectious material (as respiratory droplets) or with contact with objects or surfaces contaminated with the causative virus, and is characterized especially by fever, cough, and shortness of breath and may progress to pneumonia and respiratory failure (Merriam-Webster, n.d.-b, section 1)”.

*SARS-CoV-2* refers to “the coronavirus (Severe acute respiratory syndrome coronavirus 2 of the genus Beta-coronavirus) that is the causative agent of COVID-19 (Merriam-Webster, n.d.-d, section 1)”

*Brain fog* refers to “a usually temporary state of diminished mental capacity marked by inability to concentrate or to think or reason clearly (Merriam-Webster, n.d.-a, section 1)”

*Long-COVID* refers to “a condition that is marked by the presence of symptoms (such as fatigue, cough, shortness of breath, headache, or brain fog) which persist for an extended period of time (such as weeks or months) following a person's initial recovery from COVID-19 infection : POST-COVID SYNDROME (Merriam-Webster, n.d.-c, section 1)”.

### **SECTION THREE: MANAGING THE COLLECTED DATA**

This scholarly project included a review of 125,573 results, from which twenty-five peer-reviewed journal articles were selected, encompassing various study types such as meta-analyses, cohort studies, systematic reviews of qualitative or regulatory studies. The literature review was organized according to the levels of evidence outlined by the Melnyk framework. This author had access to the full text of all selected articles. Appendix A is a literature review matrix which contains all twenty-five peer-reviewed journal articles and their key points in article title, study purpose, sampling, methods, study results, level of evidence, limitations, and whether to use as evidence to support change in practice.

#### **SECTION FOUR: QUALITY APPRAISAL**

In addition to utilizing the peer-reviewed journal article criterion and a five-year time frame, this study used the Melnyk framework as a quality control measure.

#### **Critical Appraisal Tool**

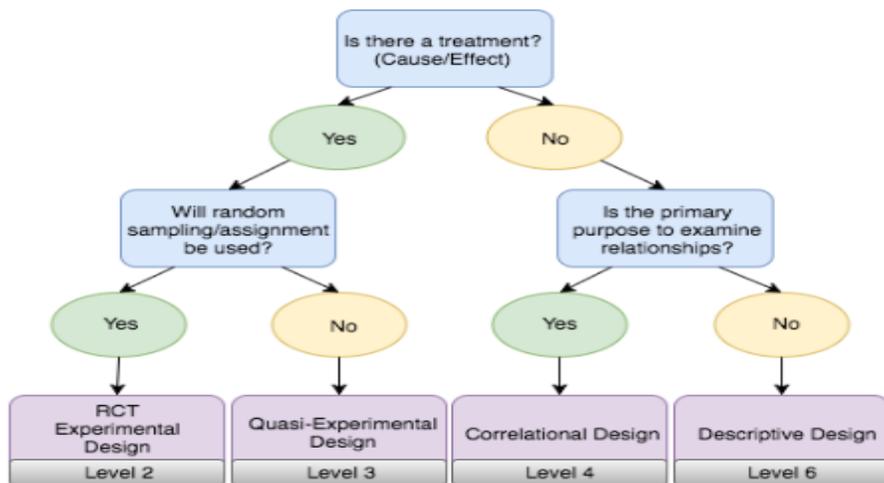

The Melnyk framework, also known as the Melnyk levels of evidence, is a tool used in evidence-based practice to evaluate the strength and quality of evidence from research studies. It consists of seven levels of evidence, each with varying degrees of reliability and rigor, and is often used to guide healthcare professionals in making clinical decisions based on the best available evidence (University of Michigan, 2022, Melnyk Levels of evidence section). Level one includes systematic review and meta-analysis of randomized controlled trials, clinical guideline based on systematic reviews or meta-analyses (University of Michigan, 2022, Melnyk levels of evidence section). Level two includes one or more randomized controlled trials (University of Michigan, 2022, Melnyk levels of evidence section). Level three includes non-

randomized sampling but controlled trial (University of Michigan, 2022, Melnyk levels of evidence section). Level four includes case-control or cohort study (University of Michigan, 2022, Melnyk levels of evidence section). Level five represents systematic review of descriptive and qualitative studies (University of Michigan, 2022, Melnyk levels of evidence section). Level six includes single descriptive or qualitative study (University of Michigan, 2022, Melnyk levels of evidence section). Level seven is for expert opinion (University of Michigan, 2022, Melnyk levels of evidence section).

A simpler way to evaluate level of evidence based on Melnyk levels of evidence is based on whether there will be a treatment. If there is a treatment involved in the study, it likely belongs to level one to level three, otherwise, the highest level will be level four.

**Figure 6**

*Level of evidence (University of Michigan, 2022, Figure 1)*

**SECTION FIVE: DATA ANALYSIS AND SYNTHESIS**

## Data Analysis

There are five articles at Melnyk framework level one of evidence (Akbarialiabad et al., 2021; Hawke et al., 2022; Jarrott et al., 2022; Moghimi et al., 2021; Theoharides, 2022), two articles at level three (Aiello et al., 2021; Rigoni et al., 2022), fifteen articles at level four (Asadi-Pooya et al., 2021; Delgado-Alonso et al., 2022; Di Stadio et al., 2022; Douaud et al., 2022; Frontera et al., 2022; Guo et al., 2022; Hellgren et al., 2021; Hugon et al., 2021; 2021; Leta et al., 2021; Mandal et al., 2020; Salihefendic et al., 2021; Østergaard, 2021), and three articles at level five (Baig, 2021; Fernández-de-las-Peñas et al., 2021; Theoharides et al., 2021), which made total of twenty-five articles in this scholarly project. Possible relationships for certain phenomena were discovered by both quantitative studies and qualitative studies at macro level / system level and micro level/ cell and neurochemistry level. Quantitative research often offered more details and provided a higher level of evidence. However, qualitative and correlational research offered great direction or hypothesis of further quantitative research. Therefore, both types of studies can be used for supporting practice changes, and quantitative data could more likely have higher influence on decision of implementing a change. For example, the article “Comparison of serum neurodegenerative biomarkers among hospitalized covid-19 patients versus non-covid subjects with normal cognition, mild cognitive impairment, or Alzheimer's dementia. Alzheimer's & Dementia”, “Long-covid syndrome-associated brain fog and chemofog: Luteolin to the rescue” “Chronic long-covid syndrome: A protracted covid-19 illness with neurological dysfunctions ”, “Could SARS-CoV-2 spike protein be responsible for long-covid syndrome? ”, and “long covid—a hypothesis for understanding the biological basis and pharmacological treatment strategy ”, all mentioned biomarkers of neuronal and glial degeneration with patients infected by SARS-CoV-2, which could be the cause of long-COVID (Baig, 2021; Frontera et al., 2022;

Jarrott et al., 2022; Theoharides et al., 2021). All of them mentioned, further study is needed (Baig, 2021; Frontera et al., 2022; Jarrott et al., 2022; Theoharides et al., 2021).

“Long COVID—a hypothesis for understanding the biological basis and pharmacological treatment strategy” and “Could SARS-CoV-2 spike protein be responsible for long-covid syndrome?”, both mentioned intracellular antioxidant, such as Luteolin, might help with preventing or treat long-COVID (Theoharides, 2022; Theoharides et al., 2021).

Quantitative research data showed that 40% to 77.9% of patients experience post-COVID symptoms or developed long-COVID syndrome (Jarrott et al., 2022; Moghimi et al., 2021). Some research showed patients’ neurologic decline even getting worse after certain time (Rigoni et al., 2022), which is opposite of what general population expected.

Some studies showed possible reason of vascular ischemia of brain which may lead to hypoxia of tissues (Salihefendic et al., 2021; Theoharides, 2022; Østergaard, 2021). Even though those studies are not all quantitative, the hypothesis of hypoxia was brought to the table. We can start thinking or implementing some patient education or activates into plan of care, such as deep breathing, due to low risk of harm to patient and potential benefit of patients.

## **Synthesis**

Numerous studies have demonstrated a clear correlation between SARS-CoV-2 infection and a decline in neurological function(Aiello et al., 2021; Asadi-Pooya et al., 2021; Baig, 2021; Delgado-Alonso et al., 2022; Di Stadio et al., 2022; Douaud et al., 2022; Fernández-de-las-Peñas et al., 2021; Frontera et al., 2022; Guo et al., 2022; Hellgren et al., 2021; Hugon et al., 2021; Leta et al., 2021; Mandal et al., 2020; Moghimi et al., 2021; Ollila et al., 2022; Rigoni et al., 2022; Salihefendic et al., 2021). Nonetheless, the underlying reasons remain uncertain, and the majority of medical professionals have not yet established or accepted any effective treatment.

The literature puts forth several hypotheses, such as inflammation-induced damage to brain or other tissue cells, vascular ischemia, hypoxia, and underlying chronic conditions (Theoharides, 2022; Theoharides et al., 2021; Østergaard, 2021). Further evaluation and higher-level studies are needed. Treatment-related experimental studies are needed urgently due to increasing cases of long-COVID syndrome (Moghimi et al., 2021).

### **Ethical Consideration**

Ethical consideration is a set of principles that guide researchers and scientists during the stages of research design and practices. It is an important part of consideration during research. However, it could be different internationally. Some countries do not require ethical approval for clinical research, but others may have very straight restrictions. For example, in article “Long-COVID symptoms and duration in SARS-CoV-2 positive children-a nationwide cohort study”, the authors pointed out that ethical approval was not requested by Danish law (Borch et al., 2022, Materials and methods section). Marta Rigoni and the team clearly stated in the article “Long-COVID results after hospitalization for SARS-CoV-2 infection” that their study was approved by the ethic committee of the Autonomous Province of Trento and followed the Declaration of Helsinki Ethical Principles for Medical Research Involving Human subjects (Jarrott et al., 2022, Ethics statement section).

In the total of twenty-five articles, there are eight articles were approved by their local government or hospital ethical committee(Aiello et al., 2021; Delgado-Alonso et al., 2022; Di Stadio et al., 2022; Douaud et al., 2022; Guo et al., 2022; Hawke et al., 2022; Hellgren et al., 2021; Ollila et al., 2022; Rigoni et al., 2022), four of them clearly stated that they did not have ethical approval based on the nature of the study (Akbarialiabad et al., 2021; Borch et al., 2022; Jarrott et al., 2022; Theoharides, 2022), and thirteen of them did not mention ethical

consideration in the research paper which includes systemic reviews (Asadi-Pooya et al., 2021; Baig, 2021; Fernández-de-las-Peñas et al., 2021; Frontera et al., 2022; Hawke et al., 2022; Hugon et al., 2021; 2021; Leta et al., 2021; Mandal et al., 2020; Moghimi et al., 2021; Salihefendic et al., 2021; Theoharides et al., 2021; Østergaard, 2021).

### **Ethical approval**

The study does not require ethical approval, because the systematic review is based on already published reports and the original data are anonymous. All of the patient information was deidentified.

## **SECTION SIX: DISCUSSION**

### **Significance and implications for Practice**

The COVID-19 pandemic, caused by the SARS-CoV-2 virus, is still ongoing. While the number of daily infections may decrease for various reasons, the number of patients suffering from long-COVID continues to rise (Theoharides et al., 2021). Quantitative research data showed from 40% to 77.9% of patients experience post-COVID symptoms or developed long-COVID syndrome (Jarrott et al., 2022; Moghimi et al., 2021). The reasons behind long-COVID remain unclear. SARS-CoV-2 infection causes brain change which is represented by cognitive functions declining was observed clinically and brain changes in certain area has been proved by image studies (Di Stadio et al., 2022; Douaud et al., 2022; Salihefendic et al., 2021). From 8.7 % to 46.7% patients reported mental clouding/brain fog after COVID-19 infection from variety studies (Aiello et al., 2021; Asadi-Pooya et al., 2021; Di Stadio et al., 2022; Guo et al., 2022; Hugon et al., 2021).

This evidence-based project has significance and relevance related to patient care in daily practice. It summarized data from high quality published articles with real symptoms observed

clinically. While pulmonary changes received extensive coverage and public attention, the topic of brain changes and declining cognitive functions did not garner the same level of prominence. Consequently, it was more susceptible to being overlooked or ignored. Nevertheless, it is important to recognize that brain cell damage resulting from cognitive decline can potentially have lasting effects on individuals' lives. It goes without saying that those experiencing a decline in cognitive function also suffer noticeable decrease in their overall quality of life. The best way to avoid this is prevention from infection of the virus. This project brought awareness to both patients and clinicians. It offers evidence-based data to prove that brain damage is not as people expected that the symptoms improve over time, but get worse (Rigoni et al., 2022). It supports the importance of wearing a high-quality mask and warning patients that even though they might not suffer from severe symptoms during acute stage of SARS-CoV-2 virus infection, there still could be a significant consequence from the infection. Asymptomatic infection should not be an excuse for lowering the level of prevention.

Another implication for practice is the need of cognitive function evaluation after COVID-19 infection. For patients who already showed symptoms of cognitive function decline, COVID-19 infection should be considered as a risk factor. The importance of prevention of COVID-19 infection should be on going in patients' education at daily practice. The brain damage should be mentioned as potential consequence to increase the public understanding and awareness. More people should be aware of the long-term consequence.

Several hypotheses have been discovered and discussed by healthcare professionals, including biomarkers of neuronal and glial degeneration with patients infected by SARS-CoV-2, which could be the cause of long-COVID (Baig, 2021; Frontera et al., 2022; Jarrott et al., 2022; Theoharides et al., 2021), vascular ischemia of brain which may lead to hypoxia of tissues

(Salihefendic et al., 2021; Theoharides, 2022; Østergaard, 2021), and COVID-19 spike protein may passing and damaging BBB and neuron (Theoharides, 2022). Some studies even showed patients' neurologic decline even getting worse after certain time (Rigoni et al., 2022), which is opposite of what general population expected. Unfortunately, no effective treatment has been discovered yet, which could be an urgent need in the current situation. Therefore, it has become imperative to expedite higher-level quantitative experimental research to address these concerns. Given the global battle against the SARS-CoV-2 virus, international cooperation may be crucial in the current situation.

### **Sustainability**

The COVID-19 global pandemic, precipitated by the SARS-CoV-2 virus, may eventually reach an official conclusion. Nevertheless, the virus persists and continues to exert its impact on afflicted individuals on a daily basis. While the mortality rate has decreased to a level that signifies progress in curbing the global pandemic, it is crucial to acknowledge the enduring long-term repercussions stemming from infection. Early detection and intervention still play an important role to keep death rate low. They may also help with long-COVID symptoms. More research of discover the relationship between early intervention or vaccine and long-COVID symptoms, especially brain damage is urgently needed in the future. No published article related to this topic was found in this project. Continuing education of the importance of prevention, such as wearing masks in medical settings, should become one of the daily practice protocols. For diseases which may cause long-term and potentially permanent damage, such as SARS-CoV-2 virus infection done to the brain, should be clearly conveyed to patients. Healthcare providers should stay updated and educated in fast changing situations, making a realistic plan

for patients to follow, and emphasizing the effective way and importance of preventing disease, not only COVID-19, but also other contiguous disease as well.

### **Dissemination plan**

The dissemination plan for this project will be multi-faceted and include multiple levels of focus. The first level involves a focus on sharing the research results with healthcare professionals. Inside of this author's practice and organizations that the author joins, discussing results from this evidence-based project could be done at weekly or monthly meetings. Outside of the author's practice or at organizations with direct connections, discussing the results from this project can be done at lunch meetings or other official or non-official meetings. For healthcare providers who do not have direct connection with the author, this author plan to publish the article and give presentation in healthcare conference to share the results from this evidence-based project with other healthcare professionals to spread out the words.

The second level focuses on sharing the research results with patients. Patient education of COVID-19 prevention will be added to the daily practice protocol where this author works. Patient education hand-outs regarding signs and symptoms of brain damage which are represented by cognitive function decline will be given to patients who have or potentially have COVID-19 infection, especially during high sickness seasons, such as winter. It will be recommended that patients who had COVID-19 infections in the past do a comprehensive cognitive evaluation, and this will be added to the daily practice at this author's practice. Early referral to a neurologist to slow down or stop the symptoms getting worse will be discussed with patients as needed.

The third level is focusing on sharing the research data with the public. A short educational video could be beneficial to the public. Putting the video on the practice's website

and social media platforms like Facebook or YouTube in parallel with hosting some public webinars could be ways to reach the goal.

### **Conclusion**

The COVID-19 pandemic, stemming from the SARS-CoV-2 virus, continues to profoundly impact daily life for individuals worldwide. While studies have been conducted on the phenomenon of long-COVID symptoms, the precise underlying causes remain elusive.

Remarkably, observations of neurological decline subsequent to SARS-CoV-2 infection have been documented. The scientific community has responded with great interest, resulting in the publication of a significant number of articles—approximately 125,573—within major research databases, exploring the subject of neurological damage and cognitive dysfunction. To contribute to this body of knowledge, this scholarly project focuses on curating 25 peer-reviewed journal articles specifically related to long-COVID and its association with changes in neurologic function, as well as potential etiological factors contributing to such changes.

Among the proposed hypotheses examined in the curated articles are the virus's ability to breach the blood-brain barrier and inflict damage upon neuronal cells, the release of neurochemicals linked to the SARS-CoV-2 antibody spike protein, as well as the occurrence of vascular ischemia, brain hypoxia, and other organ-related manifestations. Urgent attention must be directed towards further research into the treatment of chronic neurologic function alterations stemming from long-COVID, emphasizing the significance of preventive measures against COVID-19 infection in everyday practice.

		complications.		COVID-19 infection.			

**Appendix B**

**DEVELOPING A CLINICAL QUESTION**

**Patient/Problem/Population:**

neurological damage in adult COVID-19 infected patients

**Intervention:**

No intervention

**Comparison: (if applicable)**

Compare cognitive function with testing group and data base of the same age group people before COVID 19 pandemic

**Outcome:**

COVID-19 infection decreases cognitive function

**I. Based on the content above, write out your question in sentence format:**

In adult patients infected with COVID 19, does COVID 19 infection decrease patient’s cognitive function in three months?

**II. Based on your work above, make a list of possible search terms that may be used in the literature search:**

<u>COVID 19</u>	<u>long-COVID</u>	<u>SARS-CoV-2</u>
<u>Long COVID</u>	<u>Neurological damage</u>	<u>Brain function</u>
<u>Brain damage</u>	<u>hard to concentrate</u>	<u>memory loss</u>

**Appendix C**

**CITI Certificate**

Completion Date 13-Dec-2022  
Expiration Date 13-Dec-2025  
Record ID 52972994

This is to certify that:

**June Alsgaard**

Has completed the following CITI Program course:

Not valid for renewal of certification through CME.

**Biomedical Research - Basic/Refresher**  
(Curriculum Group)  
**Biomedical & Health Science Researchers**  
(Course Learner Group)  
**1 - Basic Course**  
(Stage)
